## Chapter 21

## The Accuracy of Percentages

## Confidence Intervals

## Example

There are nearly 25,000 registered voters in the county. Use a simple random sample of size 400 to estimate the percentage of registered voters who favor the sale of municipal bonds for the construction of two new elementary schools.

1. Is this a chance process? What is the box model?
2. It turns out that $55 \%$ of the voters in your sample favor the sale of bonds. What is your estimate for the entire population?
3. How accurate is your estimate? Could another sample yield a different result?
4. If you knew the box $S D$, could you find the $S E$ for the percentage of 1's drawn?
5. Can you estimate the box SD?
6. Use your estimate of the Box SD to find (approximately) the SE for the percentage of 1 's drawn?
7. Build a $95 \%$ confidence interval for the true population percentage in favor of bonds.
8. Build a $68 \%$ confidence interval for the true population percentage in favor of bonds.
9. If each student in the class were to sample 400 voters and construct a $68 \%$ confidence interval, about how many of these intervals would actually contain the true population percentage in favor of bonds?

## The Bootstrap

When we do not know what is in the box, we estimate the SD of the box by using the SD of the sample.

## Confidence Intervals

A 95\% confidence interval for the population percentage is given by

$$
\text { Sample percentage } \pm 2 \text { (SE for } \%)
$$

The confidence interval is valid if the number of draws is large enough.

For a confidence interval with a different confidence level, normal tables are used to find the multiplier.

An 80\% confidence interval is
Sample percentage $\pm 1.3$ (SE for \%)

A 90\% confidence interval is
Sample percentage $\pm 1.65$ (SE for \%)

Example. A health inspector takes a random sample of 300 10 -year-olds in a city, and finds that 73\% of them have had chicken-pox. Find a 90\% confidence interval for the percentage of 10 -year-olds in the city who have had chickenpox.

Example. Senator Smith wants to know if she should seek re-election. From a population of $1,000,000$ voters, a simple random sample of size 2500 is taken. In the sample, $53 \%$ of the voters favor Senator Smith. As her statistical consultant, what should you tell her?
